Some answers/hints to hwk.1.5

- (1) a. Diverges (both series diverge). b. Converges (bring to the common denominator).
 c. Diverges. (Note that $\sum \frac{1}{\ln^n(n)}$ converges. The convergence $\sum (\frac{1}{(n+10)\ln(n)} - \frac{1}{\ln^n(n)})$ would imply the convergence of $\sum (\frac{1}{(n+10)\ln(n)})$. Thus the $\sum (\frac{1}{(n+10)\ln(n)} - \frac{1}{\ln^n(n)})$ diverges.)
 d. Diverges for $s < 1$ (any t) and for $s = 1, t \leq 1$. Converges for $s > 1$ or $s = 1, t > 1$. (Integral comparison criterion).
 e. Diverges. f. Converges (criterion of d'Alembert). g. Diverges.
 h. Converges absolutely (comparison to $\sum \frac{1}{n^2}$).
- (2) The domains of convergence are:
 a. $|x| \leq 1$. b. $x \geq -\frac{3}{2}$. c. $x > -\frac{5}{4}$. d. $-\frac{1}{e} \leq x < \frac{1}{e}$. e. $-\frac{1}{2} \leq \sin(x) < \frac{1}{2}$.
 f. $|x + 1| \leq 1$. g. $-1 \leq x < 1$. (The divergence at $x = 1$ occurs because $\sum_{k=1}^n \frac{1}{k} < n$.)
 h. $-1 \leq x < 1$. (Let $a_n = \frac{1 \cdot 4 \cdots (3n+1)}{2 \cdot 5 \cdots (3n+2)}$. To prove the divergence at $x = 1$ we present a_n in the form $a_n = \frac{4 \cdot 7 \cdots (3n+1)}{2 \cdot 5 \cdots (3n-1)} \frac{1}{(3n+2)} > \frac{1}{(3n+2)}$. Thus, for $x = 1$ the series diverges by comparison with $\sum \frac{1}{n}$. To check the convergence at $x = -1$ we use Leibnitz's criterion, for this we should prove that $a_n \rightarrow 0$. Alternatively, we should prove: $\ln(a_n) \rightarrow -\infty$. But $\ln(a_n) = -\sum_{k=1}^n \ln(1 + \frac{1}{3k+1})$. And $\sum_{k=0}^{\infty} \ln(1 + \frac{1}{3k+1}) = \infty$ by comparison to $\sum \frac{1}{n}$. Thus $a_n \rightarrow 0$ and we use Leibnitz criterion for $x = -1$.)
 i. The series converges for any x .
- (3) a. $f(x) = -\ln(3-x)(2-x) = -\ln(6) - \ln(1 - \frac{x}{3}) - \ln(1 - \frac{x}{2}) = -\ln(6) + \sum_{n \geq 1} \frac{(\frac{x}{3})^n + (\frac{x}{2})^n}{n}$. (The series converges for $-2 \leq x < 2$)
 b. $f(x) = \frac{1 - \cos(2x)}{2} = \dots$
 c. $f(x) = \frac{1}{(1-x)^3} + \frac{x}{(1-x)^3}$. Now use the series for $\frac{1}{(1-x)^3}$, which can be obtained by the differentiation of the series for $\frac{1}{(1-x)}$.
 d. Rewrite $f(x) = \frac{\sin(2) - \sin(2x)}{2}$. Now use the series for $\sin(x)$.
 e. First obtain the series for $\arctan(x)$, using the series for $(\arctan(x))' = \frac{1}{1+x^2}$. Then substitute x^3 .
 h. Rewrite $f(x) = x \cdot \cos(x) - \sin(x)$. Now use the series for $\sin(x) \cos(x)$.
- (4) a. A counterexample: $\sum \frac{(-1)^n}{n}$.
 b. The proof goes via the main Cauchy theorem (as explained in the lectures).
 c. A counterexample: $\sum \frac{(-1)^n}{\ln(n)}$.
