will talk about

The lower tail for triangles in sparse random graphs

Abstract: Let X denote the number of triangles in the random graph $G(n, p)$. The problem of determining the asymptotic of the rate of the lower tail of X, that is, the function $f_c(n, p) = log Pr(X \geq cE[X])$ for a given $c \ni [0, 1)$, has attracted considerable attention of both the combinatorics and the probability communities. We shall present a proof of the fact that whenever $p >> n^{-1/2}$, then $f_c(n, p)$ can be expressed as a solution to a natural combinatorial optimisation problem that generalises Mantel's / Turan's theorem. This is joint work with Gady Kozma.
