Generalized Fourier Transform and Minimal representations (of p-adic groups)

Abstract: The classical Fourier transform is an ubiquitous operator acting on $L^2(V)$ for a finite-dimensional quadratic space V . We study it from the point of view of representation theory. Together with other operators it forms a remarkable representation of a metaplectic group on $L^2(V)$, that has minimal functional dimension. Minimal representation of other groups, often have models on $L^2(X)$ for a cone X . We shall see how to define generalized Fourier transforms on $L^2(X)$ and discuss their properties.
