

# Ordinary differential equations for Math

(201.1.0061. Spring 2023. Dmitry Kerner)

## Homework 3. Submission date: 13.04.2023

Questions to submit: 1.b. 2.i. 2.iii. 2.v. 4.c. 5.a. 6.b.

Homeworks must be either typed (e.g. in Latex) or written in readable handwriting and scanned in readable resolution.

- The Bernoulli equation,  $x' = g(t)x + h(t)x^{n+1}$ ,  $g, h \in C^0(a, b)$ ,  $n \neq 0, -1$ , is important for fluid transition between two reservoirs. The standard approach is to convert it to a linear equation, by substitution  $x = z^k$  near a point  $x_0 \neq 0$ .
  - Find the needed  $k$ . (Address both cases  $x_0 > 0$ ,  $x_0 < 0$ .)
  - Solve the IVP:  $x' = x \cdot \tan(t) + x^4 \cdot \cos(t)$ ,  $x(\pi) = -1$ .
- In the following cases write the general solution (at least in the form  $F(x, t) = \text{const}$ ). Draw the integral curves (you can use any software). For which initial conditions the local solution exists/is unique? What are the singular points of these curves (the points with  $\text{grad}(F) = \vec{0}$ )?
  - $x' = \frac{2t+3t^2x}{3x^2-t^3}$
  - $x' = \frac{2x}{3t} + \frac{2t}{x}$
  - $3t^2x + x^2 + 2t^3x' + 3tx \cdot x' = 0$
  - $x' = x(1 + xe^t)$
  - $tx' - 2t^2\sqrt{x} = 4x$
- Take two linear functions  $l_i(t, x) = a_it + b_ix - c_i$ ,  $i = 1, 2$ . Consider the equation  $x' = \frac{l_2(t, x)}{l_1(t, x)}$ .
  - Suppose the lines  $\{l_i(t, x) = 0\} \subset \mathbb{R}^2$  are not parallel. Shift the coordinates  $t \rightarrow t - c_t$ ,  $x \rightarrow x - c_x$  to move the line intersection to the origin. In the new coordinates the equation becomes homogeneous. Write the details. Solve the IVP:  $x' = \frac{4x-2t-6}{x+t-3}$ ,  $x(2) = 2$ .
  - If the two lines are parallel (but do not coincide) then change the coordinates  $x \rightarrow x - c \cdot t$  to get an autonomous equation. Write the details.  
Write the general solution of the equation  $x' = \frac{t-x-1}{t-x-2}$ .
- For a differentiable function  $\mathbb{R}^n \supseteq \mathcal{U} \xrightarrow{F} \mathbb{R}$  define the total differential  $dF := \sum_j \partial_j F \cdot dx_j$ .
  - Is  $x dy - y dx$  the total differential of a  $C^2$ -function?
  - Prove: if  $\sum a_j \cdot dx_j$  is the total differential of a  $C^2$  function then  $\partial_j a_i = \partial_i a_j$  for all  $i, j$ .
  - Prove: the differential forms  $\frac{xdx+ydy}{(x^2+y^2)^p}$ ,  $\frac{ydx-xdy}{(x^2+y^2)}$  are locally exact at each point of  $\mathbb{R}^2 \setminus \{0, 0\}$ .  
Let  $\mathcal{U}$  be one of:  $\mathbb{R}^2 \setminus \{0, 0\}$ ,  $\mathbb{R}_{x>0}^1 \times \mathbb{R}_y^1$ ,  $\mathbb{R}^2 \setminus \{y = 0, x \leq 0\}$ . In which cases are these forms exact on  $\mathcal{U}$ ?
- Pass from the  $(x, t)$ -coordinates to the polar coordinates  $(r, \phi)$ . Accordingly transform the equation  $x' = f(\frac{x}{t})$  into  $\frac{dr}{d\phi} = r \cdot \Phi(\phi)$ . Here the function  $\Phi$  is  $2\pi$ -periodic and possibly not defined on some (discrete) set of points. Define  $p := \int_0^{2\pi} \Phi(\phi) d\phi$ , suppose this integral converges.
  - Describe the integral curves in the cases  $p > 0$ ,  $p = 0$ ,  $p < 0$ . Prove: any local solution extends to a global one,  $\mathbb{R}^1 \xrightarrow{r(\phi)} \mathbb{R}_{\geq 0}^1$ . Conclude: in  $(x, t)$  coordinates no local solution extends to a global  $\mathbb{R}^1 \xrightarrow{x(t)} \mathbb{R}^1$ , and for some initial conditions (which?) there is no existence/uniqueness.
  - As an explicit example analyze the solutions of  $x' = \frac{C \cdot x - t}{x + C \cdot t}$ , for all constants  $C \in \mathbb{R}$ .
- Consider the equation  $f \cdot dx + g \cdot dy = 0$ . Suppose  $g(x_0, y_0) \neq 0$ .
  - Prove: there exists a local integrating factor of the form  $\lambda(x)$  iff  $\frac{f-g}{g}$  is locally independent of  $y$ . In this case  $\lambda = C \cdot e^{\int (\frac{f-g}{g}) ds}$ . (We have proved this in the class.)
  - Obtain similar results for the existence of integrating factors in the forms  $\lambda(x-y)$ ,  $\lambda(x^2+y^2)$ .
  - Solve the equations: i.  $(t^2 - x^2 + 1) + (t^2 - x^2 - 1)x' = 0$ , ii.  $ydx - (x^2 + y^2 + x)dy = 0$ .
