A DICHOTOMY FOR BOUNDED DISPLACEMENT AND CHABAUTY-FELL CONVERGENCE OF DISCRETE SETS

YOTAM SMILANSKY AND YAAR SOLOMON

Abstract. We prove that in every compact space of Delone sets in \( \mathbb{R}^d \) which is minimal with respect to the action by translations, either all Delone sets are uniformly spread, or continuously many distinct bounded displacement equivalence classes are represented, none of which contains a lattice. The implied limits are taken with respect to the Chabauty-Fell topology on the space of closed subsets of \( \mathbb{R}^d \). This topology coincides with the standard local topology in the finite local complexity setting, and it follows that the dichotomy holds for all minimal spaces of Delone sets associated with well-studied constructions such as cut-and-project sets and substitution tilings, whether or not finite local complexity is assumed.

A main step in the proof is a result concerning Delone sets as limits of converging sequences of finite patches with respect to the Chabauty-Fell topology, under the assumption of minimality. In the infinite local complexity setting, information on a converging sequence does not immediately imply information regarding finite patches in the limit Delone set, and we provide sufficient conditions under which certain qualitative and quantitative information can be deduced.

1. Introduction

A set \( \Lambda \subset \mathbb{R}^d \) is called a Delone set if it is both uniformly discrete and relatively dense, that is, if there are constants \( r, R > 0 \) so that every ball of radius \( r \) contains at most one point of \( \Lambda \) and \( \Lambda \) intersects every ball of radius \( R \). We refer to \( r \) and \( R \) as the separation constant and the packing radius of \( \Lambda \), respectively. Two Delone sets \( \Lambda, \Gamma \subset \mathbb{R}^d \) are said to be bounded displacement (BD) equivalent if there exists a bijection \( \phi : \Lambda \rightarrow \Gamma \) satisfying

\[
\sup_{x \in \Lambda} \| x - \phi(x) \| < \infty.
\]

Such a mapping \( \phi \) is called a BD-map. All lattices in \( \mathbb{R}^d \) with the same covolume are BD-equivalent, and a Delone set \( \Lambda \) is called uniformly spread if it is equivalent to a lattice, or equivalently, if there is a BD-map \( \phi : \Lambda \rightarrow \alpha \mathbb{Z}^d \), for some \( \alpha > 0 \).

Fix a metric \( \rho \) on \( \mathbb{R}^d \) and consider the space \( \text{Cl}(\mathbb{R}^d) \) of closed subsets of \( \mathbb{R}^d \). The Chabauty-Fell topology on \( \text{Cl}(\mathbb{R}^d) \) is the topology induced by the metric

\[
D(\Lambda_0, \Lambda_1) \overset{\text{def}}{=} \inf \left\{ \varepsilon > 0 \left| \frac{\Lambda_0 \cap B(0, 1/\varepsilon)}{\Lambda_1 \cap B(0, 1/\varepsilon)} \cup \{1\} \right\}, \quad (1.1)
\]

where \( B(x, R) \) is the open ball of radius \( R > 0 \) centered at \( x \in \mathbb{R}^d \) with respect to the metric \( \rho \), and \( A^{(\varepsilon)} \) is the \( \varepsilon \) neighborhood of the set \( A \). This metric was introduced by Chabauty [Ch] for \( \text{Cl}(\mathbb{R}^d) \), as well as for a more general setting, and later extended by Fell [Fe], see also [LSt] for the relation to the Hausdorff metric. In this work we only consider metrics \( \rho \) that are determined by norms on \( \mathbb{R}^d \), and although different choices of norms result in different metrics \( D \), they all define the same Chabauty-Fell topology. We remark
that in the aperiodic order literature, this topology is often referred to as the local rubber topology, see e.g. [BG, §5].

Delone sets in $\mathbb{R}^d$ are elements of $\text{Cl}(\mathbb{R}^d)$, and we may consider compact spaces of Delone sets, where the implied limits are taken with respect to the Chabauty-Fell topology. Such a space $X$ of Delone sets in $\mathbb{R}^d$ is minimal with respect to the $\mathbb{R}^d$ action by translations if the orbit closure of every Delone set $\Lambda \in X$ is dense in $X$.

Denote the cardinality of the set of BD-equivalence classes represented in $X$ by $\text{BD}(X)$. The following dichotomy is our main result.

**Theorem 1.1.** Let $X$ be a space of Delone sets in $\mathbb{R}^d$, and assume it is compact with respect to the Chabauty-Fell topology and minimal with respect to the action of $\mathbb{R}^d$ by translations. Then either

1. there exists a uniformly spread Delone set in $X$ (and so every $\Lambda \in X$ is uniformly spread and $\text{BD}(X) = 1$),

or

2. $\text{BD}(X) = 2^{\aleph_0}$,

where $2^{\aleph_0}$ denotes the cardinality of the continuum.

Observe that the minimality assumption is essential, as shown by the following simple example. Consider $\Lambda = (-2\mathbb{N}) \sqcup \{0\} \sqcup \mathbb{N}$, a Delone set in $\mathbb{R}$. Then the orbit closure $X$ of $\Lambda$ under translations by $\mathbb{R}$ and with respect to the Chabauty-Fell topology, consists of translations of $\Lambda$, the orbit closure of $\mathbb{Z}$ and the orbit closure of $2\mathbb{Z}$. Therefore $\text{BD}(X) = 3$, and indeed $X$ is not minimal.

Let us remark that the implication in the brackets of (1) of Theorem 1.1 is a direct consequence of [La, Theorem 1.1], see also [FG, Theorem 3.2] for a sketch of a similar proof that holds for general minimal spaces of Delone sets. In addition, we note that a uniformly discrete set in $\mathbb{R}^d$ with separation constant $r > 0$ is BD-equivalent to a subset of the lattice $r^2 \mathbb{Z}^d$, hence the upper bound $\text{BD}(X) \leq 2^{\aleph_0}$ is trivial.

Recall that a Delone set $\Lambda$ is of finite local complexity (FLC) if for every $R > 0$ the number of distinct patterns that are contained in balls of radius $R$ in $\Lambda$ up to translations is finite. For such sets the orbit closure under translations is sometimes called the hull, and every Delone set in the hull is also FLC. The hull itself is then called FLC, and the Chabauty-Fell topology on $X$ coincides with the standard local topology, see [BG, §5]. It follows that Theorem 1.1 holds also for FLC spaces with respect to the standard local topology. In particular, Theorem 1.1 answers question (1) in [FG, §7] in the strongest possible way.

In addition to Theorem 1.1, we establish two results that may be of interest in their own right. In §2 we prove Theorem 2.3, the converse of the implication of Theorem 2.2 which first appeared in [FSS]. In §3 we prove Theorem 3.3 that deals with convergence of a sequence of patches in the Chabauty-Fell topology. A main obstacle when working with this topology is that generally, the limit object does not have to contain patches that are close in the Hausdorff metric to the elements of the converging sequence, which makes it hard to say something about patches in the limit object. Theorem 3.3 gives sufficient conditions allowing for certain information concerning patches in the limit object to be deduced in minimal spaces of Delone sets. This constitutes one of the main steps of Theorem 1.1.

Delone sets are mathematical models of atomic positions, and BD-equivalence offers a natural way of classifying them. BD-equivalence for general discrete point sets was
previously considered mainly in the context of uniformly spread point sets, see e.g. [DO1, DO2, La] and [DSS]. More recently, BD-equivalence emerged as an important object of study for Delone sets that appear in the study of mathematical quasicrystals and aperiodic order, see [BG] for a comprehensive introduction to such constructions. For cut-and-project sets, BD-equivalence was studied in [HKW], and links to the notions of bounded remainder sets and pattern equivariant cohomology appeared in [FG, HK, HKK] and in [KS1, KS2], respectively. For Delone sets associated with substitution tilings, sufficient conditions for a set to be uniformly spread were provided in [ACG], [S1] and [S2]. In addition, for the multiscale substitution tilings introduced by the authors in [SS], it was shown that any Delone set associated with an incommensurable tiling cannot be uniformly spread.

Recently, questions regarding BD-non-equivalence between two Delone sets were considered in [FSS], and a sufficient condition for BD-non-equivalence was established. It was later shown in [S3] that if the eigenvalues and eigenspaces of the substitution matrix satisfy a certain condition, then the tiling space contains continuously many distinct BD-classes.

The following less restrictive equivalence relation on Delone sets is often studied in parallel to the BD-equivalence relation. We say that two Delone sets \( \Lambda \) and \( \Gamma \) are biLipschitz equivalent if there exists a biLipschitz bijection between them. Namely, a bijection \( \varphi : \Lambda \to \Gamma \) and a constant \( C \geq 1 \) so that

\[
\forall x, y \in \Lambda \quad \frac{1}{C} \leq \frac{\| \varphi(x) - \varphi(y) \|}{\| x - y \|} \leq C.
\]

It was shown by Burago and Kleiner [BK] and independently by McMullen [McM], that there exist Delone sets in \( \mathbb{R}^d \), \( d \geq 2 \), that are not biLipschitz equivalent to \( \mathbb{Z}^d \). Magazinov showed in [Mag] that there are continuously many Delone sets that are pairwise non-biLipschitz equivalent. It would be interesting to obtain an analogue of our Theorem 1.1 in this context.

**Question.** Does Theorem 1.1 hold if one replaces the BD-equivalence relation by biLipschitz equivalence?

**1.1. Consequences of Theorem 1.1.** Theorem 1.1 directly implies that \( \text{BD}(\mathbb{X}) = 2^{80} \) for many special families of minimal spaces of Delone sets which are central in the theory of aperiodic order, and for which the BD-equivalence relation was previously considered.

**1.1.1. Substitution tilings:** For primitive substitution tilings of \( \mathbb{R}^d \), we denote by \( \lambda_1 > |\lambda_2| \geq \ldots \geq |\lambda_n| \) the eigenvalues of the substitution matrix, and we let \( t \geq 2 \) be the minimal index such that the eigenspace of \( \lambda_t \) contains non-zero vectors whose sum of coordinates is not zero. Under the assumption that tiles are bi-Lipschitz homeomorphic to closed balls, it was shown in [S2, Theorem 1.2 (I)] that if

\[
|\lambda_t| > \lambda_1^{(d-1)/d}
\]

then the Delone sets corresponding to the tilings in the tiling space are not uniformly spread. Under the assumption (1.2) and an additional assumption regarding the existence of certain patches, it was recently shown in [SS] that \( \text{BD}(\mathbb{X}) = 2^{80} \). Given the above result of [S2], and since substitution tiling spaces are minimal (see [BG]), the following strengthening of the main result of [SS] is a direct consequence of our Theorem 1.1.
Corollary 1.2. Let $\mathcal{X}$ be a primitive substitution tiling space with tilings by tiles that are bi-Lipschitz homeomorphic to closed balls. Assume that condition (1.2) holds, then $\text{BD}(\mathcal{X}) = 2^{\aleph_0}$.

Note that in the context of tilings, we say that two tilings are BD-equivalent if their corresponding Delone sets, which are obtained by picking a point from each tile, are BD-equivalent. In addition to the above, [S2] contains an example of a substitution rule, for which the eigenvalues of the substitution matrix satisfy
\[ |\lambda_2| = \lambda_1^{(d-1)/d} \tag{1.3} \]
and the corresponding Delone sets are not uniformly spread, see [S2, Theorem 1.2 (III)]. Note that in this example the main result of [S3] cannot be applied.

Corollary 1.3. There exists a primitive substitution tiling space $\mathcal{X}$ for which condition (1.3) holds and $\text{BD}(\mathcal{X}) = 2^{\aleph_0}$.

1.1.2. Cut-and-project sets: Theorem 1.2 in [HKW] concerns the BD-equivalence relation in the context of cut-and-project sets that arise from linear toral flows (which constitute an equivalent method of constructing cut-and-project sets, see [ASW, Proposition 2.3]). Since the hull of a cut-and-project set is minimal, the corollary below follows directly from [HKW, Theorem 1.2 (III)] and our Theorem 1.1. We refer to [HKW] for more details on the construction and terminology.

Corollary 1.4. For almost every $(k - d)$-dimensional linear section $S$, which is a parallelootope in the $k$-dimensional torus, there is a residual set of $d$-dimensional subspaces $V$ for which the hull of the corresponding cut-and-project set contains continuously many distinct BD-classes.

In [FG, §6] Frettlöh and Garber introduced the half-Fibonacci sets. These are cut-and-project sets in $\mathbb{R}$ that belong to the same hull, but due to their Theorem 6.4 are not BD-equivalent to each other. In particular, they are not uniformly spread (see [FG, Theorem 3.2]). We thus obtain the following result.

Corollary 1.5. Let $\mathcal{X}$ be the hull of the half-Fibonacci sets from [FG]. Then $\text{BD}(\mathcal{X}) = 2^{\aleph_0}$.

1.1.3. Multiscale substitution tilings: Multiscale substitution tilings were recently studied in [SS]. Under an incommensurability assumption on the underlying substitution scheme, the corresponding tiling spaces are minimal and their associated Delone sets, which are never FLC, are not uniformly spread. In view of this, our Theorem 1.1 implies the following.

Corollary 1.6. Let $\mathcal{X}$ be an incommensurable multiscale tiling space. Then $\text{BD}(\mathcal{X}) = 2^{\aleph_0}$.

2. Necessary and sufficient conditions for BD-non-equivalence

2.1. Notations. Bold figures will be used to denote vectors in $\mathbb{R}^d$, and we will use the supremum norm $\|\cdot\|_\infty$ on $\mathbb{R}^d$ throughout this document. Note that with respect to this norm, balls are (Euclidean) cubes, and we use both terms interchangeably. We denote by $\partial A, |A|$ and $\text{vol}(A)$ the boundary, cardinality and Lebesgue measure of a set $A \subset \mathbb{R}^d$, respectively, and we denote by $\# S$ the cardinality of a finite set $S$. Given $\varepsilon > 0$ and $A \subset \mathbb{R}^d$ we denote the $\varepsilon$-neighborhood of $A$ by
\[ A^{(+\varepsilon)} \overset{\text{def}}{=} \{ x \in \mathbb{R}^d \mid \text{dist}(x, A) \leq \varepsilon \}, \]
where $\text{dist}(x, A) = \inf\{\|x - a\|_\infty \mid a \in A\}$. For an integer $m > 0$ we denote by
\[
Q_d(m) \overset{\text{def}}{=} \left\{ \sum_{i=1}^{d} [a_i, a_i + m) \mid a_1, \ldots, a_d \in m\mathbb{Z} \right\},
\]
the collection of all half-open cubes in $\mathbb{R}^d$ with edge-length $m$ and with vertices in $m\mathbb{Z}^d$, and we denote by $Q_d^*(m)$ the collection of finite unions of elements from $Q_d(m)$. In the case $m = 1$ we simply write $Q_d$ and $Q_d^*$. For $A \in Q_d$ the notation $\text{vol}_{d-1}(\partial A)$ stands for the $(d-1)$-Lebesgue measure of $\partial A$. The following lemma is a direct consequence of Lemmas 2.1 and 2.2 of [La].

**Lemma 2.1.** Let $F \in Q_d^*$ and let $s > 0$, then
\[
\text{vol}\left((\partial F)^{(s)}\right) \leq c_0 \cdot s^d \cdot \text{vol}_{d-1}(\partial F),
\]
where $c_0$ depends only on $d$.

### 2.2. BD-equivalence.

The following condition for non-BD-equivalence of two Delone sets in $\mathbb{R}^d$ was given in [FSS].

**Theorem 2.2.** [FSS, Theorem 1.1] Let $\Lambda_0, \Lambda_1$ be two Delone sets in $\mathbb{R}^d$ and suppose that there is a sequence $(A_m)_{m \in \mathbb{N}}$ of sets $A_m \in Q_d^*$ for which
\[
\frac{|\#(\Lambda_0 \cap A_m) - \#(\Lambda_1 \cap A_m)|}{\text{vol}_{d-1}(\partial A_m)} \xrightarrow{m \to \infty} 0.
\]
Then there is no BD-map $\phi : \Lambda_0 \to \Lambda_1$.

For the converse, we have the following result (compare [La, Lemma 2.3]).

**Theorem 2.3.** Let $\Lambda_0, \Lambda_1$ be two Delone sets in $\mathbb{R}^d$ and suppose that there is no BD-map between $\Lambda_0$ and $\Lambda_1$. Then there is a sequence $(A_m)_{m \in \mathbb{N}}$ of sets $A_m \in Q_d^*$ such that
\[
\frac{|\#(\Lambda_0 \cap A_m) - \#(\Lambda_1 \cap A_m)|}{\text{vol}_{d-1}(\partial A_m)} \xrightarrow{m \to \infty} \infty.
\]

**Proof.** Suppose that there is no BD-map between $\Lambda_0$ and $\Lambda_1$, that is, no bijection $\phi : \Lambda_0 \to \Lambda_1$ that satisfies
\[
\sup_{x \in \Lambda_0} \|x - \phi(x)\|_\infty < \infty.
\]

For every $m \in \mathbb{N}$ consider the bipartite graph $G_m \overset{\text{def}}{=} (\Lambda_0 \cup \Lambda_1, E_m)$, where
\[
E_m = \left\{ (x, y) \mid x \in \Lambda_0, y \in \Lambda_1, \|x - y\|_\infty \leq 2m \right\}.
\]

The existence of a perfect matching in $G_m$ for some $m$ would imply the existence of a BD-map between $\Lambda_0$ and $\Lambda_1$, contradicting our assumption. Thus by Hall’s marriage theorem (see e.g. [Ra]), for every $m \in \mathbb{N}$ there is a set $X_m \subset \Lambda_{i_m}$, $i_m \in \{0, 1\}$, so that $|X_m| > |(X_{m+2}^{i_m+1} \cap \Lambda_{1-i_m})|$. Fix $m \in \mathbb{N}$, and assume without loss of generality that $i_m = 0$. Set
\[
A_m \overset{\text{def}}{=} \bigcup \{ Q \in Q_d(m) \mid Q \cap X_m \neq \emptyset \} \in Q_d^*(m).
\]
For $Q \in Q_d(m)$ let $Q'$ be a cube of edge-length $3m$ which is concentric with $Q$, and set
\[
B_m \overset{\text{def}}{=} \bigcup \{ Q' \mid Q \in Q_d(m), Q \cap X_m \neq \emptyset \} \in Q_d^*(m).
\]
Clearly $B_m \supset A_m \supset X_m$, and by the triangle inequality we have $X_m^{(2m)} \supset B_m$. Therefore

$$\#(A_0 \cap A_m) > # (A_1 \cap B_m) = # (A_1 \cap A_m) + # (A_1 \cap (B_m \setminus A_m)),$$

which implies

$$\#(A_0 \cap A_m) - # (A_1 \cap A_m) > # (A_1 \cap (B_m \setminus A_m)). \quad (2.4)$$

It is left to show that $# (A_1 \cap (B_m \setminus A_m))/vol_{d-1}(\partial A_m) \xrightarrow{m \to \infty} \infty$, which is a consequence of the following argument, taken from the proof of [La, Lemma 2.3]. We repeat Laczkovich’s reasoning for completeness.

Denote by $Q_1, \ldots, Q_n \in Q_d(m)$ the $m$-cubes whose union is $A_m$ and write $\partial A_m = \bigcup_{j=1}^s F_j$, where each $F_j$ is a $(d-1)$-dimensional face of some $Q_{i_j}$. For each $1 \leq j \leq s$ let $P_j \in Q_d(m)$ be the reflection of $Q_{i_j}$ about $F_j$. Then $P_j \subset B_m \setminus A_m$ for every $j$, and in the sequence $P_1, \ldots, P_s$ the same cube can appear at most $2d$ times, the number of possible reflections. Then

$$2d \cdot \text{vol}(B_m \setminus A_m) \geq \sum_{j=1}^s \text{vol}(P_j) = s \cdot m^d = m \cdot s \cdot m^{d-1} = m \cdot vol_{d-1}(\partial A_m). \quad (2.5)$$

Recall that $\Lambda_1$ is a Delone set and let $R_1 \in \mathbb{N}$ be so that every cube of edge-length $R_1$ contains a point of $\Lambda_1$. For simplicity, assume that $m$ is an integer multiple of $R_1$. Consider the distinct elements of $Q_d(m)$ whose union is $B_m \setminus A_m$. Each of these cubes contains at least $(m/R_1)^d$ points of $\Lambda_1$. Then

$$\#(A_1 \cap (B_m \setminus A_m)) \geq \frac{\text{vol}(B_m \setminus A_m)}{R_1^d} \geq \frac{m}{2dR_1^d} \cdot vol_{d-1}(\partial A_m). \quad (2.6)$$

Combining (2.4) and (2.6) yields (2.2) with the sequence $(A_m)_{m \in \mathbb{N}}$ defined by (2.3). \hfill \Box

**Corollary 2.4.** Let $(A_m)_{m \in \mathbb{N}}$ be a sequence of sets as in (2.2), then for every $R > 0$ there exists $M > 0$ so that for every $m \geq M$ each $A_m$ contains a ball of radius $R$.

**Proof.** Let $R > 0$ and suppose that there is a sequence $m_j \to \infty$ such that for every $j$ the set $A_{m_j}$ does not contain a ball of radius $R$. Then for every $j$ we have $A_{m_j} \subset (\partial A_{m_j})^{(+R)}$ and thus by Lemma 2.1

$$\text{vol}(A_{m_j}) \leq c_0 \cdot R^d \cdot vol_{d-1}(\partial A_{m_j}). \quad (2.7)$$

Since $\Lambda_0$ and $\Lambda_1$ are uniformly discrete and relatively dense, there exist constants $a, b > 0$ so that for every $j$

$$a \cdot \text{vol}(A_{m_j}) \leq \#(A_0 \cap A_{m_j}), \#(A_1 \cap A_{m_j}) \leq b \cdot \text{vol}(A_{m_j}). \quad (2.8)$$

Combining (2.7) and (2.8) implies that for every $j$ we have

$$\frac{|\#(A_0 \cap A_{m_j}) - \#(A_1 \cap A_{m_j})|}{\text{vol}_{d-1}(\partial A_{m_j})} \leq (b - a)c_0 \cdot R^d,$$

contradicting (2.2). \hfill \Box
3. The topology on spaces of Delone sets

We consider the dynamical system \((X, d, G)\), where \((X, d)\) is a compact metric space and \(G\) is a group acting on \(X\). The dynamical system \((X, d, G)\) is called minimal if every \(G\)-orbit, \(G x \overset{\text{def}}{=} \{gx \mid g \in G\}\) for \(x \in X\), is dense in \((X, d)\). A set \(S \subset G\) is called syndetic if there is a compact set \(K \subset G\) so that for every \(g \in G\) there is a \(k \in K\) with \(kg \in S\). Note that when \(G = \mathbb{R}^d\) this notion coincides with our definition of a relatively dense set. A point \(x_0 \in X\) is said to be uniformly recurrent if for every open neighborhood \(U\) of \(x_0\) the set of ‘return times’ to \(U\), \(\{g \in G \mid g x_0 \in U\}\), is syndetic. As shown in [Fu] Theorem 1.15, in minimal systems every point is uniformly recurrent.

Recall that given a metric \(\rho\) on \(\mathbb{R}^d\) we may use (1.1) to define a metric \(D\) on \(\text{Cl}(\mathbb{R}^d)\), the space of closed subsets of \((\mathbb{R}^d, \rho)\), and that this metric induces the Chabauty-Fell topology. Here and in what follows we take \(\rho\) to be the metric defined by the supremum norm \(\|\cdot\|_\infty\) on \(\mathbb{R}^d\). Note that replacing it with any other norm on \(\mathbb{R}^d\), such as the Euclidean norm, would change the metric \(D\) but not the induced Chabauty-Fell topology, also known as the local rubber topology in the context of aperiodic order. It is known that \(D\) is a complete metric on \(\text{Cl}(\mathbb{R}^d)\), and the space \((\text{Cl}(\mathbb{R}^d), D)\) is compact, see e.g. [dH], [LS].

Let \(X\) be a collection of Delone sets in \(\mathbb{R}^d\). Under the additional assumptions that \(X\) is a closed subset of \(\text{Cl}(\mathbb{R}^d)\) and that \(\mathbb{R}^d\) acts on \(X\) by translations, the space \((X, D, \mathbb{R}^d)\) is a compact dynamical system. We say that \(\Lambda \in X\) is almost repetitive if for every \(x \in \mathbb{R}^d\) and \(\varepsilon > 0\) there exists \(R = R(\varepsilon, x) > 0\) such that every ball \(B(y, R)\) in \(\mathbb{R}^d\) contains a vector \(v \in \mathbb{R}^d\) that satisfies

\[
D(\Lambda - x, \Lambda - v) < \varepsilon.
\]

In words, for every \(x \in \mathbb{R}^d\) and \(\varepsilon > 0\) there exists \(R > 0\) so that a copy of \(B(0, 1/\varepsilon) \cap (\Lambda - x)\) can be found in every \(R\)-ball, up to wiggling each point by at most \(\varepsilon\). We also refer to [FR] Definitions 2.8, 2.13, 3.5] and to [LP] for distinctions between similar definitions of repetitivity.

The observation in Lemma 3.1 is useful when working with the metric \(D\) in spaces of uniformly discrete point sets.

**Lemma 3.1.** Suppose that \(\Lambda_0, \Lambda_1 \subset \mathbb{R}^d\) are uniformly discrete sets with separation constant \(r > 0\), and that \(D(\Lambda_0, \Lambda_1) < \varepsilon\) for \(0 < \varepsilon < r/2\). Then for every set \(A \subset B(0, 1/\varepsilon)\) that is a translated copy of an element of \(Q_\varepsilon^d\), there exist injective maps

\[
\varphi_0 : \Lambda_0 \cap A \to A \cap A^{(+\varepsilon)}, \quad \varphi_1 : \Lambda_1 \cap A \to A_0 \cap A^{(+\varepsilon)},
\]

that satisfy

\[
\forall x \in \Lambda_0 \cap A : \quad \|x - \varphi_0(x)\|_\infty < \varepsilon, \quad \forall y \in \Lambda_1 \cap A : \quad \|y - \varphi_1(y)\|_\infty < \varepsilon. \quad (3.1)
\]

In particular, there is a constant \(c_1\) that depends on \(d\) and \(r\) so that

\[
|\#(\Lambda_0 \cap A) - \#(\Lambda_1 \cap A)| \leq c_1 \cdot \varepsilon^d \cdot \text{vol}_{d-1}(\partial A). \quad (3.2)
\]

**Proof.** Given \(A \subset B(0, 1/\varepsilon)\) as above, since \(D(\Lambda_0, \Lambda_1) < \varepsilon\), the existence of \(\varphi_0, \varphi_1\) satisfying (3.1) follows directly from the definition of \(D\) in (1.1). Note that the maps are injective since \(\varepsilon < r/2\). Therefore

\[
|\#(\Lambda_0 \cap A) - \#(\Lambda_1 \cap A)| \leq \#(\Lambda_0 \cap (\partial A)^{(+\varepsilon)}) + \#(\Lambda_1 \cap (\partial A)^{(+\varepsilon)}).
\]

Since \(\Lambda_0\) and \(\Lambda_1\) are uniformly discrete and in view of Lemma 2.1 (3.2) follows. \(\Box\)
We remark that if \( \Lambda \) is a Delone set in \( \mathbb{R}^d \) with separation constant and packing radius \( r, R > 0 \), and if \( X \) is the orbit closure of \( \Lambda \) with respect to \( D \), then every \( \Gamma \in X \) is a Delone set with separation constant at least \( r \) and packing radius at most \( R \).

The following lemma shows that minimal spaces are uniformly almost repetitive. Namely, the radius \( R(\mathbf{x}, \varepsilon) \) from the definition of almost repetitivity above does not depend on \( \mathbf{x} \).

**Lemma 3.2.** Let \( X \) be a compact space of Delone sets so that the dynamical system \( (X, D, \mathbb{R}^d) \) is minimal. Then for every \( \varepsilon > 0 \) there exists \( R = R(\varepsilon) > 0 \), so that for every \( \Lambda, \Gamma \in X \) and \( y \in \mathbb{R}^d \), there exists some \( \mathbf{v} \in B(y, R) \) for which

\[
D(\Gamma, \mathbf{\Lambda} - \mathbf{v}) < \varepsilon.
\]

**Proof.** Let \( \varepsilon > 0 \), and let \( \Lambda \in X \) and \( \mathbf{x} \in \mathbb{R}^d \). By minimality, the set \( \mathbf{\Lambda} - \mathbf{x} \) is uniformly recurrent. For \( \eta > 0 \) denote \( U^\mathbf{x}_\eta = \{ \mathbf{\Lambda}' \in X \mid D(\mathbf{\Lambda} - \mathbf{x}, \mathbf{\Lambda}') < \eta \} \), then the set \( \{ \mathbf{v} \in \mathbb{R}^d \mid \mathbf{\Lambda} - \mathbf{v} \in U^\mathbf{x}_\varepsilon \} \) is relatively dense (syndetic). In other words, there exists \( \mathcal{R}^\varepsilon \) such that every cube of edge-length \( \mathcal{R}^\varepsilon \) contains some \( \mathbf{v} \in \mathbb{R}^d \) satisfying \( D(\mathbf{\Lambda} - \mathbf{x}, \mathbf{\Lambda} - \mathbf{v}) < \varepsilon / 2 \).

By minimality again, the collection \( \{ \mathbf{\Lambda} - \mathbf{x} \mid \mathbf{x} \in \mathbb{R}^d \} \) is dense in \( X \). Thus \( \{ U^\mathbf{x}_\varepsilon \}_{\mathbf{x} \in \mathbb{R}^d} \) is an open cover of \( X \), and by compactness there exists a finite sub-cover \( U^{\mathbf{x}_1}_\varepsilon, \ldots, U^{\mathbf{x}_n}_\varepsilon \). Then for every \( \Gamma \in X \) these exist some \( j \in \{ 1, \ldots, n \} \) so that \( \Gamma \in U^{\mathbf{x}_j}_\varepsilon \), and hence \( D(\Gamma, \mathbf{\Lambda} - \mathbf{x}_j) < \varepsilon / 2 \). Setting \( R = \max \{ \mathcal{R}^{\mathbf{x}_j}_\varepsilon / 2, \ldots, \mathcal{R}^{\mathbf{x}_n}_\varepsilon / 2 \} \), it follows that for every \( \mathbf{y} \in \mathbb{R}^d \) there exists some \( \mathbf{v} \in B(\mathbf{y}, \mathcal{R}^{\mathbf{x}_j}_\varepsilon / 2) \subset B(\mathbf{y}, R) \) such that \( D(\mathbf{\Lambda} - \mathbf{x}_j, \mathbf{\Lambda} - \mathbf{v}) < \varepsilon / 2 \). Then by the triangle inequality \( D(\Gamma, \mathbf{\Lambda} - \mathbf{v}) < \varepsilon \), as required. \( \square \)

A patch in a Delone set \( \Lambda \) is a finite subset of \( \Lambda \). In the FLC setup it is often convenient to define specific elements in the orbit closure of \( \Lambda \), also known as the hull, as nested unions of patches. In such a case the limit set contains all the patches in the sequence. In contrast to the FLC case and in addition to other difficulties that arise in the non-FLC setup, the fact that two sets are close with respect to the metric \( D \) in [1.1] only gives information about behavior inside a large ball. In particular, convergence of a sequence of patches \( (Q_m)_{m \in \mathbb{N}} \) to a limit \( \Gamma \) does not imply that \( \Gamma \) contains any of the \( Q_m \)'s as sub-patches, or even a patch that is close to any of the \( Q_m \)'s in the sense of Hausdorff distance.

**Theorem 3.3.** Let \( X \) be a minimal space of Delone sets in \( \mathbb{R}^d \), \( \Lambda \in X \), \( (A_m)_{m \in \mathbb{N}} \) a sequence of sets in \( \mathcal{Q}^d \) and \( (\varepsilon_m)_{m \geq 0} \) a sequence of positive constants with \( \varepsilon_0 < \frac{r(\Lambda)}{2} \), where \( r(\Lambda) \) is the separation constant of \( \Lambda \). Assume that the following properties hold for every \( m \in \mathbb{N} \):

1. There exists \( \mathbf{x}_m \in \mathbb{R}^d \) such that \( A_m \subset B(\mathbf{x}_m, 1/2 \varepsilon_m) \).
2. There exists \( \mathbf{y}_m \in \mathbb{R}^d \) such that \( B(\mathbf{y}_m, 2R(\varepsilon_{m-1})) \subset A_m \), where \( R(\varepsilon) \) is as in Lemma 2.

Then there exist \( \mathbf{u}_m \in B(\mathbf{y}_m, R(\varepsilon_{m-1})) \) and patches \( Q_m = (\Lambda \cap A_m) - \mathbf{u}_m \) such that \( \lim_{m \to \infty} Q_m = \Gamma \in \mathbb{R}^d \). Moreover, for every \( m \geq 2 \)

\[
B(\mathbf{0}, R(\varepsilon_{m-1})) \subset A_m - \mathbf{u}_m \subset B(\mathbf{0}, 1/\varepsilon_m),
\]

\[
D(\Lambda - \mathbf{u}_{m-1}, \mathbf{\Lambda} - \mathbf{u}_m) < \varepsilon_{m-1},
\]

\[
D(Q_m, \Gamma) < \varepsilon_{m-1}
\]
and there exists \( c_2 > 0 \) so that

\[
\left| \# (\Gamma \cap (A_m - u_m)) - \# Q_m \right| \leq c_2 \cdot \varepsilon_m^d \cdot \text{vol}_{d-1}(\partial A_m),
\]

where \( c_2 \) depends on the dimension \( d \) and separation constant \( r(\Lambda) \).

Proof. First observe that by assumptions (1) and (2) we have \( 2R(\varepsilon_m) \leq 1/2\varepsilon_{m+1} \) for every \( m \in \mathbb{N} \). It follows from Lemma 3.2 that \( R(\varepsilon) > 1/\varepsilon \) for every \( \varepsilon > 0 \), and so we obtain

\[
\varepsilon_{m+1} \leq \frac{1}{4R(\varepsilon_m)} \leq \frac{1}{4}\varepsilon_m.
\]

(3.7)

In particular, the series \( \sum_{m=1}^{\infty} \varepsilon_m \) is convergent.

We define the vectors \( u_m \), and hence the patches \( Q_m \), inductively.

- By (1), \( A_1 \) is in particular contained in a ball of radius \( 1/\varepsilon_1 \). Let \( u_1 \) be such that

\[ Q_1 = (\Lambda \cap A_1) - u_1 \text{ is contained in } B(0, 1/\varepsilon_1). \]

Assume that the vectors \( u_j \), and thus the patches \( Q_j = (\Lambda \cap A_j) - u_j \), are defined for \( j \in \{1, \ldots, m\} \) such that for every \( 2 \leq j \leq m \) we have

(i) \( B(0, R(\varepsilon_{j-1})) \subset A_j - u_j \subset B(0, 1/\varepsilon_j) \).

(ii) \( D(\Lambda - u_j, \Lambda - u_{j-1}) < \varepsilon_{j-1} \).

We define \( u_{m+1} \) as follows.

- By (2), \( A_{m+1} \) contains a ball of the form \( B(y_{m+1}, 2R(\varepsilon_m)) \). By Lemma 3.2 let \( u_{m+1} \in B(y_{m+1}, R(\varepsilon_m)) \) be a vector satisfying

\[
D(\Lambda - u_m, \Lambda - u_{m+1}) < \varepsilon_m.
\]

(3.8)

Thus (ii) for \( j = m + 1 \) holds. Note that since \( B(y_{m+1}, 2R(\varepsilon_m)) \subset A_{m+1} \) and \( u_{m+1} \in B(y_{m+1}, R(\varepsilon_m)) \) we have

\[
B(0, R(\varepsilon_m)) \subset A_{m+1} - u_{m+1}.
\]

(3.9)

By (1), \( A_{m+1} - u_{m+1} \subset B(x_{m+1} - u_{m+1}, 1/2\varepsilon_{m+1}) \) and by (3.9) \( A_{m+1} - u_{m+1} \) contains the origin. Then by the triangle inequality, \( A_{m+1} - u_{m+1} \) is contained in \( B(0, 1/\varepsilon_{m+1}) \), completing the proof of (i) for \( j = m + 1 \).

This completes the construction of the vectors \( u_m \) and the patches \( Q_m \). Next we show that the sequence \( (Q_m)_{m \in \mathbb{N}} \) is a Cauchy sequence. Fix some \( \varepsilon > 0 \) and let \( M \) be so that \( 2\varepsilon_M < \varepsilon \). Let \( m > n > M \), and note that by property (ii) we have \( D(\Lambda - u_{k+1}, \Lambda - u_k) < \varepsilon_k \), for every \( k \geq M \). Then by the triangle inequality,

\[
D(\Lambda - u_m, \Lambda - u_n) \leq \sum_{k=n}^{m-1} D(\Lambda - u_{k+1}, \Lambda - u_k) < \varepsilon_n < 2\varepsilon_n < 2\varepsilon_M < \varepsilon,
\]

(3.10)

where the third inequality follows from (3.7). By property (i), for every \( j \in \mathbb{N} \) the point sets \( Q_j \) and \( \Lambda - u_j \) in particular coincide on the ball \( B(0, 1/\varepsilon_{j-1}) \). Since \( m, n > M \), the sets \( \Lambda - u_n \) and \( Q_n \) coincide on \( B(0, 1/\varepsilon) \), and similarly for \( \Lambda - u_m \) and \( Q_m \). Therefore, relying on (3.10), for every \( m > n > M \) we have

\[
D(Q_m, Q_n) \leq D((\Lambda - u_m) \cap B(0, 1/\varepsilon), (\Lambda - u_n) \cap B(0, 1/\varepsilon)) < \varepsilon.
\]

(3.11)

Thus \( (Q_m)_{m \in \mathbb{N}} \) is a Cauchy sequence. The space \( (X, D) \) is complete, as a compact metric space, hence the limit \( \Gamma = \lim_{m \to \infty} Q_m = \lim_{m \to \infty} \Lambda - u_m \) exists and belongs to \( X \).

It is left to prove (3.3), (3.4), (3.5) and (3.6). First observe that (3.3) and (3.4) follow immediately from the construction, see properties (i) and (ii). To see (3.5), let \( m \in \mathbb{N} \).
Let \( k > m \) be so that \( D(Q_k, \Gamma) < \varepsilon_m \). Repeating the computations in (3.10) and (3.11) yields that \( D(Q_m, Q_k) < 2\varepsilon_m \), and by (3.7) we have
\[
D(Q_m, \Gamma) \leq D(Q_m, Q_k) + D(Q_k, \Gamma) < 3\varepsilon_m < \varepsilon_{m-1}.
\]

Finally, we prove (3.6). By (3.3) we have \( A_m - u_m \subset B(0,1/\varepsilon_m) \) and by (3.5) we have \( D(\Gamma, Q_{m+1}) < \varepsilon_m \). Thus by Lemma 3.1 with \( A = A_m - u_m \) we obtain
\[
|\#(\Gamma \cap (A_m - u_m)) - \#(Q_{m+1} \cap (A_m - u_m))| \leq c_1 \cdot \varepsilon_m^d \cdot \text{vol}_{d-1}(\partial A_m).
\]  

By (3.4) we have \( D(\Lambda - u_m, \Lambda - u_{m+1}) < \varepsilon_m \), and applying Lemma 3.1 once again we get
\[
|\#( (\Lambda - u_{m+1}) \cap (A_m - u_m)) - \#( (\Lambda - u_m) \cap (A_m - u_m)) | \leq c_1 \cdot \varepsilon_m^d \cdot \text{vol}_{d-1}(\partial A_m).
\]

By the definition of the \( Q_m \)'s, and since \( A_m - u_m \subset A_{m+1} - u_{m+1} \) by (3.3), this is exactly
\[
|\#(Q_{m+1} \cap (A_m - u_m)) - \#Q_m| \leq c_1 \cdot \varepsilon_m^d \cdot \text{vol}_{d-1}(\partial A_m).
\]  

Combining (3.12) and (3.13) yields (3.6) and completes the proof of the theorem. \( \square \)

4. Finding patches with large discrepancy

The goal of this chapter is to prove the following proposition, which will be used in our proof of Theorem 1.1 in \( \S 5 \).

**Proposition 4.1.** Let \( \Lambda \subset \mathbb{R}^d \) be a non-uniformly spread Delone set. Then there exist a sequence \((A_m)_{m \in \mathbb{N}}\) of sets in \( Q^*_d \) and a sequence \((x_m)_{m \in \mathbb{N}}\) of vectors in \( \mathbb{R}^d \) so that
\[
\lim_{m \to \infty} \frac{|\#(\Lambda \cap A_m) - \#(\Lambda \cap (A_m + x_m))|}{\text{vol}_{d-1}(\partial A_m)} = 0.
\]  

4. Finding patches with large discrepancy

Let \( \Lambda \subset \mathbb{R}^d \) be a Delone set. We define the central lower density and the central upper density of \( \Lambda \) respectively by
\[
\Delta_*(\Lambda) \overset{\text{def}}{=} \liminf_{t \to \infty} \frac{\#(B(0,t) \cap \Lambda)}{\text{vol}(B(0,t))}, \quad \Delta^*(\Lambda) \overset{\text{def}}{=} \limsup_{t \to \infty} \frac{\#(B(0,t) \cap \Lambda)}{\text{vol}(B(0,t))}.
\]

If the limit \( \lim_{t \to \infty} \#(B(0,t) \cap \Lambda) / \text{vol}(B(0,t)) \) exists, it is called the central density of \( \Lambda \) and is denoted by \( \Delta(\Lambda) \).

We begin with the following lemma.

**Lemma 4.2.** Let \( \Lambda \) be a Delone set, \( \gamma > 0 \) and \( A \in Q^*_d \). Then for every \( \varepsilon > 0 \) there exists \( K > 0 \) such that for every integer \( k \geq K \):

1. if \( \frac{\#(\Lambda \cap B(0,k))}{\text{vol}(B(0,k))} \geq \gamma \) then the ball \( B(0,k) \) contains \( A + x \), a translated copy of \( A \) with \( x \in \mathbb{Z}^d \), such that
\[
\frac{\#(\Lambda \cap (A + x))}{\text{vol}(A)} \geq \gamma - \varepsilon.
\]

2. if \( \frac{\#(\Lambda \cap B(0,k))}{\text{vol}(B(0,k))} \leq \gamma \) then the ball \( B(0,k) \) contains \( A + x \), a translated copy of \( A \) with \( x \in \mathbb{Z}^d \), such that
\[
\frac{\#(\Lambda \cap (A + x))}{\text{vol}(A)} \leq \gamma + \varepsilon.
\]
Proof. This is a simple averaging argument. We prove property (1), the proof of property (2) is similar.

Denote by \( \rho \) the diameter of the set \( A \). For a large integer \( k \) we write \( B(0, k) = B([-\rho], (\partial B)([+\rho]), \) where \( B([-\rho]), (\partial B)([+\rho]) \in \mathbb{Q}_d^2 \) are defined by

\[
B([-\rho]) \overset{\text{def}}{=} \bigcup \{ Q \in \mathbb{Q}_d \mid Q \subset B(0, k), \text{dist}(Q, \partial B(0, k)) > \rho \} \tag{4.2}
\]

\[
(\partial B)([+\rho]) \overset{\text{def}}{=} B(0, k) \setminus B([-\rho]),
\]

where \( \text{dist}(X, Y) \overset{\text{def}}{=} \inf \{ \| x - y \|_D \mid x \in X, y \in Y \} \).

Given \( \varepsilon > 0 \) we pick \( K \in \mathbb{N} \) large enough so that for every integer \( k \geq K \) we have

\[
\frac{\text{vol}((\partial B)([+\rho]))}{\text{vol}(B(0, k))} < \frac{\varepsilon}{2}. \tag{4.3}
\]

Let \( k \geq K \) such that

\[
\frac{\#(\Lambda \cap B(0, k))}{\text{vol}(B(0, k))} \geq \gamma, \tag{4.4}
\]

and let \( N_k \overset{\text{def}}{=} \{ x \in \mathbb{Z}^d \mid A + x \subset B(0, k) \} \). By way of contradiction, assume that

\[
\forall x \in N_k : \quad \#(\Lambda \cap (A + x)) < (\gamma - \varepsilon)\text{vol}(A). \tag{4.5}
\]

Notice that the number of cubes from \( \mathbb{Q}_d \) that form \( A \) is \( \text{vol}(A) \). Then by counting the points of \( \Lambda \) (with multiplicity) in all the sets \( A + x, x \in N_k \), the points in every unit lattice cube in \( B([-\rho]) \) is counted exactly \( \text{vol}(A) \) times. Thus

\[
\# N_k (\gamma - \varepsilon)\text{vol}(A) \overset{\text{4.5}}{\geq} \sum_{x \in N_k} \#(\Lambda \cap (A + x)) \geq \text{vol}(A) \cdot \#(\Lambda \cap B([-\rho])). \tag{4.6}
\]

Note that \( \# N_k \leq \text{vol}(B(0, k)) \), then dividing both sides of \( \text{4.6} \) by \( \text{vol}(A) \cdot \text{vol}(B(0, k)) \) yields

\[
\gamma - \varepsilon > \frac{\# (\Lambda \cap B([-\rho]))}{\text{vol}(B(0, k))} \overset{\text{4.2}}{\geq} \frac{\#(\Lambda \cap B(0, k))}{\text{vol}(B(0, k))} - \frac{\#(\Lambda \cap (\partial B)([+\rho]))}{\text{vol}(B(0, k))} \overset{\text{4.3}, \text{4.4}}{\geq} \gamma - \frac{\varepsilon}{2},
\]

a contradiction. \( \square \)

Lemma 4.3. Suppose that \( \Lambda \) is a Delone set in \( \mathbb{R}^d \) and that \( \Delta_\varepsilon(\Lambda) < \Delta^*(\Lambda) \). Then there exist \( \alpha < \beta \), integers \( a_k \to \infty \) and \( x_k \in \mathbb{Z}^d \) such that

\[
\frac{\# (\Lambda \cap B(0, a_k))}{\text{vol}(B(0, a_k))} \leq \alpha \quad \text{and} \quad \frac{\# (\Lambda \cap B(x_k, a_k))}{\text{vol}(B(x_k, a_k))} \geq \beta.
\]

Proof. By the assumption on the densities, there exist sequences \( a_k, b_l \to \infty \) so that

\[
\lim_{k \to \infty} \frac{\# (\Lambda \cap B(0, a_k))}{\text{vol}(B(0, a_k))} = \bar{\alpha} \quad \text{and} \quad \lim_{l \to \infty} \frac{\# (\Lambda \cap B(0, b_l))}{\text{vol}(B(0, b_l))} = \bar{\beta},
\]

where \( \bar{\alpha} < \bar{\beta} \). Since \( \Lambda \) is uniformly discrete, and since the \( (d-1) \)-volume of the boundary of a cube grows slower than the cube’s volume, we may assume that the numbers \( a_k, b_k \) are integers. Let \( \delta < \frac{\bar{\alpha} - \bar{\beta}}{2} \) and fix \( K \in \mathbb{N} \) such that for every \( k, l \geq K \) we have

\[
\frac{\# (\Lambda \cap B(0, a_k))}{\text{vol}(B(0, a_k))} \leq \bar{\alpha} + \delta \quad \text{and} \quad \frac{\# (\Lambda \cap B(0, b_l))}{\text{vol}(B(0, b_l))} \geq \bar{\beta} - \delta. \tag{4.7}
\]
For every $k$, applying Lemma 4.2 with $A = B(0, a_k)$, $\varepsilon = \frac{\beta - \alpha}{3} - \delta > 0$, and $\beta - \delta$ in the role of $\gamma$, and combining this with (4.7), we find a large enough $l = l_k$ and $x_k \in \mathbb{Z}^d$ so that $B(0, b_l)$ contains the ball $B(x_k, a_k)$, which satisfies
\[
\frac{\# (\Lambda \cap B(x_k, a_k))}{\text{vol}(B(x_k, a_k))} \geq (\beta - \delta) - \varepsilon = \beta - \frac{\beta - \alpha}{3}.
\] (4.8)

Setting $\alpha \overset{\text{def}}{=} \tilde{\alpha} + \frac{\beta - \alpha}{3}$ and $\beta \overset{\text{def}}{=} \tilde{\beta} - \frac{\beta - \alpha}{3}$, the assertion follows from (4.7) and (4.8). \square

Proof of Proposition 4.1. Let $\Lambda \subset \mathbb{R}^d$ be a non-uniformly spread Delone set. In view of Lemma 4.3, we may further assume that $\Delta = \Delta(\Lambda)$ exists. For $\alpha \neq \Delta^{-1/d}$ the Delone sets $\alpha \mathbb{Z}^d$ and $\Lambda$ do not have the same central density and hence there is no BD-map between them (see e.g. [ESS, Corollary 3.2]). By our assumption on $\Lambda$, there is no BD-map between $\Lambda$ and $\Delta^{-1/d} \mathbb{Z}^d$ as well. Applying Theorem 2.3 on these two Delone sets we obtain a sequence $(A_m)_{m \in \mathbb{N}}$ of sets in $\mathcal{Q}^d_{\alpha}$ that satisfies
\[
\frac{\#(\Delta^{-1/d} \mathbb{Z}^d \cap A_m) - \#(\Lambda \cap A_m)}{\text{vol}_{d-1}(\partial A_m)} \xrightarrow{m \to \infty} \infty.
\]

By passing to a subsequence of $(A_m)_{m \in \mathbb{N}}$ we may assume that
\[
\frac{\#(\Delta^{-1/d} \mathbb{Z}^d \cap A_m) - \#(\Lambda \cap A_m)}{\text{vol}_{d-1}(\partial A_m)} \xrightarrow{m \to \infty} \infty,
\] (4.9)
and complete the proof using (1) of Lemma 4.2. In the case that $\#(\Delta^{-1/d} \mathbb{Z}^d \cap A_m) < \#(\Lambda \cap A_m)$ for all large values of $m$, the proof is similar using (2) of Lemma 4.2 instead of (1).

For every $m \in \mathbb{N}$ we pick $\varepsilon_m$ such that
\[
\varepsilon_m \text{vol}(A_m) < \text{vol}_{d-1}(\partial A_m)
\] (4.10)
and apply Lemma 4.2 with $\gamma = \Delta - \varepsilon_m$, $A = A_m$ and $\varepsilon = \varepsilon_m$. Note that since $\Delta(\Lambda) = \Delta$ exists, the condition $\frac{\#(\Lambda \cap B(0, k))}{\text{vol}(B(0, k))} \geq \Delta - \varepsilon_m$ is satisfied for any sufficiently large $k$. By (1) of Lemma 4.2 in particular, there exists some $K_m \in \mathbb{N}$ and a vector $x_m \in \mathbb{Z}^d$ so that $A_m + x_m \subset B(0, K_m)$ and
\[
\frac{\#(\Lambda \cap (A_m + x_m))}{\text{vol}(A_m)} \geq \Delta - 2\varepsilon_m.
\] (4.11)

By (4.9)
\[
\frac{\#(\Delta^{-1/d} \mathbb{Z}^d \cap A_m) - \#(\Lambda \cap (A_m + x_m))}{\text{vol}_{d-1}(\partial A_m)} + \frac{\#(\Lambda \cap (A_m + x_m)) - \#(\Lambda \cap A_m)}{\text{vol}_{d-1}(\partial A_m)} \xrightarrow{m \to \infty} \infty.
\] (4.12)

Note that
\[
\#(\Delta^{-1/d} \mathbb{Z}^d \cap A_m) \leq \Delta \cdot \text{vol}(A_m) + c \cdot \text{vol}_{d-1}(\partial A_m),
\]
where $c$ depends on $d$ and $\Delta$, and by (4.11) we also have
\[
(\Lambda \cap (A_m + x_m)) \geq (\Delta - 2\varepsilon_m)\text{vol}(A_m).
\]
Then
\[
\frac{\#(\Delta^{-1/d} \mathbb{Z}^d \cap A_m) - \#(\Lambda \cap (A_m + x_m))}{\text{vol}_{d-1}(\partial A_m)} \leq c \cdot \text{vol}_{d-1}(\partial A_m) + 2\varepsilon_m\text{vol}(A_m) \leq c \cdot \text{vol}_{d-1}(\partial A_m),
\] (4.13)
where \( c' \) depends on \( d \) and \( \Delta \). Thus plugging (4.13) in (4.12) completes the proof of Proposition 4.1. \( \square \)

5. PROOF OF THEOREM 1.1

This chapter contains the proof of Theorem 1.1. Let \( \Lambda \subset \mathbb{R}^d \) be a non-uniformly spread Delone set and let \( A_m \in Q_d^* \) and \( x_m \in \mathbb{Z}^d \) be the sets and vectors that were constructed in Proposition 4.1. Let \( \varepsilon_m > 0 \) be so that \( A_m \) is contained in a ball of radius \( 1/2\varepsilon_m \). It follows from Corollary 2.4 that equation (4.1) implies that for every \( R \) there exists \( M \) so that \( A_m \) contains a ball of radius \( R \) for every \( m \geq M \). Then by passing to subsequences \((A_{m,j})_{j \in \mathbb{N}}, (x_{m,j})_{j \in \mathbb{N}}\) and \( (\varepsilon_{m,j})_{j \in \mathbb{N}} \), we may assume that the set \( A_{m,j} \) contains a ball of radius \( 2R(\varepsilon_{m,j-1}) \). To simplify notations we keep using the lower index \( m \) for this new sequence, and so we have a sequence \((A_m)_{m \in \mathbb{N}}\) that satisfies Proposition 4.1, and \( y_m, z_m \in \mathbb{R}^d \) for which

\[
B(y_m, 2R(\varepsilon_m-1)) \subset A_m \subset B(z_m, 1/2\varepsilon_m).
\]

Denote

\[
B_m \overset{\text{def}}{=} A_m + x_m, \quad p_m \overset{\text{def}}{=} y_m + x_m, \quad q_m \overset{\text{def}}{=} z_m + x_m.
\]

Then

\[
B(p_m, 2R(\varepsilon_m-1)) \subset B_m \subset B(q_m, 1/2\varepsilon_m).
\]

By (4.1), there is a sequence of constants \( \mu_m \to \infty \) such that

\[
|\#(\Lambda \cap A_m) - \#(\Lambda \cap (A_m + x_m))| = \mu_m \cdot \text{vol}_{d-1}(\partial A_m).
\]

Since \( \mu_m \to \infty \), by passing to a further subsequence mutually for \( A_m, x_m, \varepsilon_m \) and \( \mu_m \), we may assume that \( \mu_m \) approaches infinity in an extremely fast rate. In particular, by defining every element in the sequence with dependence on the previous one, we may assume that

\[
\frac{R(\varepsilon_m-1)^d}{\mu_m} \xrightarrow{m \to \infty} 0.
\]

Using these notations, Theorem 1.1 follows from Lemmas 5.1 and 5.2 below.

Lemma 5.1. Let \( \mathcal{X} \) be a minimal space of Delone sets and assume that there exists \( \Lambda \in \mathcal{X} \) that is non-uniformly spread. Let \((A_m)_{m \in \mathbb{N}}\) and \((B_m)_{m \in \mathbb{N}}\) be the sequences of sets in \( Q_d^* \) defined in Proposition 4.1 and in (5.2), with respect to \( \Lambda \). For every word \( \omega \in \{A,B\}^\infty \) let \((C_m)_{m \in \mathbb{N}}\) be the sequence of sets in \( Q_d^* \) defined by

\[
C_m \overset{\text{def}}{=} \begin{cases} A_m, & \omega(m) = A \\ B_m, & \omega(m) = B, \end{cases}
\]

where \( w(m) \) is \( m \)th letter in \( w \). Then there exists a sequence \((u_m)_{m \in \mathbb{N}}\) of vectors in \( \mathbb{R}^d \) so that \( \Lambda_\omega = \lim_{m \to \infty}(\Lambda \cap C_m) - u_m \) is a Delone set in \( \mathcal{X} \),

\[
u_m \in \begin{cases} B(y_m, R(\varepsilon_m-1)), \quad \omega(m) = A \\ B(p_m, R(\varepsilon_m-1)), \quad \omega(m) = B, \end{cases}
\]

and

\[
\forall m \geq 2: \quad |\#(\Lambda_\omega \cap (C_m - u_m)) - \#(\Lambda \cap C_m)| \leq c_3 \cdot \text{vol}_{d-1}(\partial C_m),
\]

where \( c_3 \) is a constant that depends on \( d \) and on the separation constant \( r(\Lambda) \).
Proof. Given $\omega \in \{A, B\}^\mathbb{N}$, consider the sequence $(C_m)_{m\in\mathbb{N}}$ of sets in $\mathbb{Q}^*_d$ defined by (5.6). By (5.1) and (5.3), conditions (1) and (2) of Theorem 3.3 are being satisfied for $(C_m)_{m\in\mathbb{N}}$, with $(\varepsilon_m)_{m\in\mathbb{N}}$ as described at the beginning of this section. Applying Theorem 3.3 we obtain vectors $u_m$ satisfying (5.7), for which the sequence of patches $Q_m \overset{\text{def}}{=} (\Lambda \cap C_m) - u_m$ is convergent. Setting $\Lambda_\omega$ to be the limit set, it is left to obtain (5.8). Indeed, by (3.6) of Theorem 3.3, for every $m \geq 2$ we have

$$|\#(\Lambda_\omega \cap (C_m - u_m)) - \#Q_m| \leq c_3 \cdot \varepsilon_m^d \cdot \text{vol}_{d-1}(\partial C_m),$$

(5.9)

where $c_3$ depends on $d$ and on $r(\Lambda)$. Clearly $\#Q_m = \#(\Lambda \cap C_m)$, thus (5.9) implies (5.8) and the proof is complete.

Lemma 5.2. Let $\mathbb{X}$ be a minimal space of Delone sets and assume that there exists $\Lambda \in \mathbb{X}$ that is non-uniformly spread. Let $\eta, \sigma \in \{A, B\}^\mathbb{N}$ be two words that differ in infinitely many places. Then the Delone sets $\Lambda_\eta$ and $\Lambda_\sigma$, which are defined in Lemma 5.1, are BD-non-equivalent.

Proof. Let $\eta, \sigma \in \{A, B\}^\mathbb{N}$ be two sequences that differ in infinitely many places. For simplicity, we assume that $\eta(m) \neq \sigma(m)$ for every $m \in \mathbb{N}$, which can be achieved by taking a subsequence of the indices, entailing no loss of generality to the remainder of the proof. We use an upper index of $\eta$ or $\sigma$ on elements of $\mathbb{Q}^*_d$ and on vectors, e.g. $C_m^\eta$ and $u_m^\eta$, to distinguish between those elements that come from the construction of $\Lambda_\eta$ and of $\Lambda_\sigma$ in Lemma 5.1.

Let $\tilde{u}_m^\eta \in \mathbb{Z}^d$ be an integer vector which is closest to $u_m^\eta$, then $F_m \overset{\text{def}}{=} C_m^\eta - \tilde{u}_m^\eta$ is an element of $\mathbb{Q}^*_d$ and

$$|\#(\Lambda_\eta \cap F_m) - \#(\Lambda_\eta \cap (C_m^\eta - u_m^\eta))| \leq c_4 \cdot \text{vol}_{d-1}(\partial F_m),$$

where by (2.1), $c_4$ is a constant depending on $d$ and on $r(\Lambda)$. Combining this with (5.8) for $w = \eta$ we obtain that

$$\forall m \geq 2: \quad |\#(\Lambda_\eta \cap F_m) - \#(\Lambda \cap C_m^\eta)| \leq (c_3 + c_4) \cdot \text{vol}_{d-1}(\partial F_m)$$

(5.10)

Next observe that for every $m \geq 2$ there exists some $v_m \in \mathbb{R}^d$ so that

$$(C_m^\eta - u_m^\eta) - v_m = C_m^\sigma - u_m^\sigma \quad \text{and} \quad \|v_m\|_\infty \leq 2R(\varepsilon_{m-1})$$

(5.11)

Indeed, assume without loss of generality that $\eta(m) = A$ and $\sigma(m) = B$, then combining (5.2), (5.6) and (5.7) yields that $C_m^\eta = A_m, C_m^\sigma = A_m + x_m, u_m^\eta \in B(y_m + R(\varepsilon_{m-1}))$ and $u_m^\sigma \in B(y_m + x_m, R(\varepsilon_{m-1})), \Lambda_\sigma$, which implies (5.11). By (5.11), the symmetric difference of $C_m^\sigma - u_m^\sigma$ and $F_m$ satisfies

$$\forall m \geq 2: \quad (C_m^\sigma - u_m^\sigma) \Delta F_m \subset \partial F_m^{(c_5 \cdot R(\varepsilon_{m-1}))},$$

and hence by (2.1)

$$\forall m \geq 2: \quad |\#(\Lambda_\sigma \cap F_m) - \#(\Lambda_\sigma \cap (C_m^\sigma - u_m^\sigma))| \leq c_6 \cdot R(\varepsilon_{m-1})^d \cdot \text{vol}_{d-1}(\partial F_m),$$

where $c_5, c_6$ depends on $d$ and on $r(\Lambda)$. Again by (5.8), this time with $w = \sigma$, we obtain

$$\forall m \geq 2: \quad |\#(\Lambda_\sigma \cap F_m) - \#(\Lambda \cap C_m^\sigma)| \leq (c_3 + c_6 \cdot R(\varepsilon_{m-1})^d) \cdot \text{vol}_{d-1}(\partial F_m).$$

(5.12)
In view of (5.10), (5.12) and the triangle inequality, for every $m \geq 2$ we have
\[
|\#(\Lambda_{\eta} \cap F_m) - \#(\Lambda_{\sigma} \cap F_m)| \geq \left| \#(\Lambda \cap C_{m}^{\eta}) - \#(\Lambda \cap C_{m}^{\sigma}) \right| - \left| \#(\Lambda_{\eta} \cap F_m) - \#(\Lambda \cap C_{m}^{\eta}) \right| - \left| \#(\Lambda_{\sigma} \cap F_m) - \#(\Lambda \cap C_{m}^{\sigma}) \right|
\]
\[
= \left| \#(\Lambda \cap C_{m}^{\eta}) - \#(\Lambda \cap C_{m}^{\sigma}) \right| - c_7 \cdot R(\varepsilon_{m-1})^d \cdot \text{vol}_{d-1}(\partial F_m),
\]
where $c_7$ depends on $d$ and $r(\Lambda)$. Since $C_{m}^{\eta} = A_m, C_{m}^{\sigma} = A_m + x_m$ and $\text{vol}_{d-1}(\partial A_m) = \text{vol}_{d-1}(\partial F_m)$, by (5.4) we have
\[
|\#(\Lambda \cap C_{m}^{\eta}) - \#(\Lambda \cap C_{m}^{\sigma})| = \mu_m \cdot \text{vol}_{d-1}(\partial F_m).
\]
Combining (5.13) and (5.14) we see that
\[
|\#(\Lambda_{\eta} \cap F_m) - \#(\Lambda_{\sigma} \cap F_m)| \geq \left( \mu_m - c_7 \cdot R(\varepsilon_{m-1})^d \right) \text{vol}_{d-1}(\partial F_m).
\]
Therefore, by (5.4), (5.5) and (5.15) we obtain
\[
\frac{|\#(\Lambda_{\eta} \cap F_m) - \#(\Lambda_{\sigma} \cap F_m)|}{\text{vol}_{d-1}(\partial F_m)} \geq \left( \mu_m \left( 1 - \frac{c_7 \cdot R(\varepsilon_{m-1})^d}{\mu_m} \right) \right) \xrightarrow{m \to \infty} \infty.
\]
Theorem 2.2 then implies that the Delone sets $\Lambda_{\eta}$ and $\Lambda_{\sigma}$ are BD-non-equivalent, as required. \hfill \Box

Given Lemma 5.2, Theorem 1.1 follows.

Proof of Theorem 1.1. Let $X$ be a minimal space of Delone sets. If there exists a uniformly spread $\Lambda \in X$, then as noted in [1], every $\Lambda \in X$ is uniformly spread, and (1) holds.

Otherwise, there exists some $\Lambda \in X$ that is non-uniformly spread. Consider the equivalence relation on $\{A, B\}$ in which $\eta \sim \sigma$ if $\eta$ and $\sigma$ differ in only finitely many places, and let $\Omega \subset \{A, B\}$ be a set of equivalence class representatives. Since every equivalence class in this relation is countable, $|\Omega| = 2^{2\aleph_0}$. For every two distinct words $\eta, \sigma \in \Omega$, Lemma 5.2 implies that $\Lambda_{\eta}$ and $\Lambda_{\sigma}$ are BD-non-equivalent, therefore BD($X$) $\geq 2^{2\aleph_0}$. As explained in [1], the upper bound is trivial, and so the proof is complete. \hfill \Box
